

NF-κB

Nuclear factor kappa-light chain enhancer of activated B-cells (NFκB) plays a key role in several aspects of the complex process of inflammatory response. Classically the regulation of pro-inflammatory cytokines has made NFκB appear to be an appealing target for the development of new anti-inflammatory drugs. However, more recent research has shown that halting inflammation by blocking NFκB may be far from simple. NFκB influences not just pro-inflammatory processes like cytokine production or leukocyte production but also can contribute to the mechanisms that control the magnitude and duration of inflammatory response in both pro- and anti-inflammatory roles depending upon conditions and context. More study is needed to understand the mechanisms and effects of NFκB *in vivo* to determine the true potential of this molecule as a therapeutic target.
